

1

Parameter selection in Leonardo

2 Both Leonardo-DeStripe and Leonardo-Fuse are distributed with well-tested default pa-
3 rameter settings that were optimized across diverse volumetric microscopy datasets
4 and are sufficient for most practical applications. In typical use cases, no parameter ad-
5 justment is required.

6 In more challenging imaging conditions, however, selective tuning of a small num-
7 ber of user-adjustable parameters may further improve performance or adapt the
8 method to specific acquisition characteristics. Importantly, these parameters primarily
9 modulate the trade-off between artifact suppression and preservation of genuine biologi-
10 cal structures, for Leonardo-DeStripe, as well as computational efficiency, for both Leo-
11 nardo-DeStripe and Leonardo-Fuse.

12 Below, we describe the key user-adjustable parameters in each module, explain
13 their functional roles, and outline recommended strategies for incremental adjustment. A
14 complete technical description of all parameters is provided in the online documentation
15 (<https://leonardo-toolset.readthedocs.io/en/latest/api.html>).

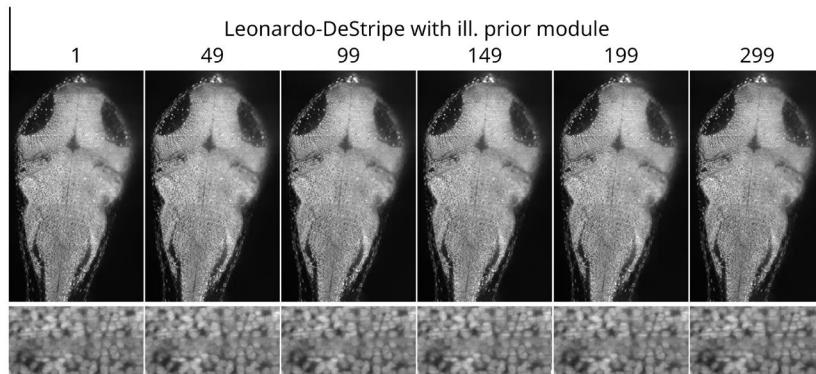

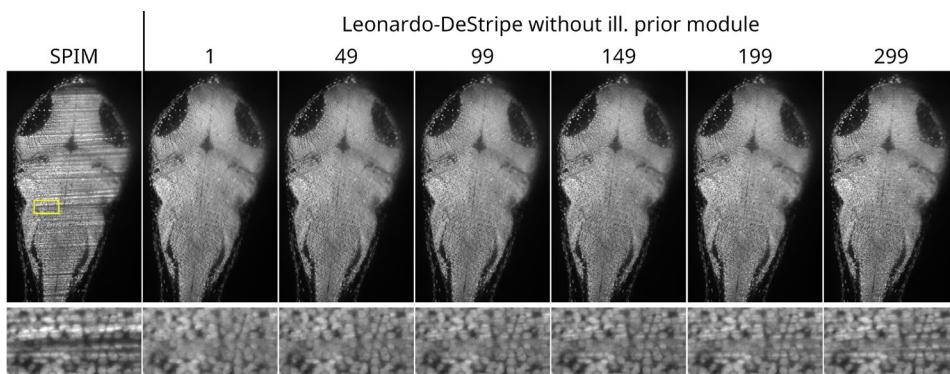

16 1 Leonardo-DeStripe: parameter discussion and practical tuning

17 Leonardo-DeStripe is designed to operate robustly with a single set of default parame-
18 ters, which were used unchanged across all datasets presented in this work. In our ex-
19 periments, we did not observe cases of catastrophic failure or instability of the destriping
20 procedure. However, in particularly challenging datasets—such as those with irregular
21 stripe orientations, drifting illumination, or biological structures strongly aligned with the
22 stripe direction—the balance between stripe suppression and structure preservation
23 may require minor adjustment. Such adjustment is typically not required to prevent fail-
24 ure of the method, but rather to refine performance when residual stripe patterns remain
25 visible or when genuine structures appear slightly attenuated.

26 Key parameters controlling the suppression–preservation trade-off

27 ● **`illu_orient` (str, optional): Activates the ill. prior in the post-processing,**
28 **which was introduced to explicitly preserve genuine biological structures that**
29 **align with the stripe direction.** This prior incorporates knowledge of the illumina-
30 tion orientation to prevent unintended attenuation of elongated features during
31 stripe suppression. When illumination direction is known, enabling this parameter
32 improves structural fidelity, particularly in datasets where biological structures are
33 directionally aligned with illumination-induced stripe patterns.

- 34 ● **`allow_stripe_deviation` (bool, default = False): Enables an additional pen-**
 35 **alty within ill. prior to account for non-ideal stripe patterns**, such as slightly
 36 tilted, wavy, or drifting stripes. When set to True, the method applies stronger sup-
 37 pression of irregular or unstable stripe artifacts. However, it may slightly reduce fine
 38 structural detail, particularly in regions containing weak or thin features. We recom-
 39 mend enabling this option only when stripe patterns deviate from a stable, straight
 40 orientation and residual artifacts persist after standard parameter adjustment. For
 41 datasets with well-aligned and stable stripe structures, keeping this parameter False
 42 better preserves structural fidelity. This parameter is effective only when the ill. prior
 43 is activated via `illu_orient`.
- 44 ● **`guided_upsample_kernel` (int, default = 49): Controls the window size of the**
 45 **guided upsampling strategy in the post-processing module.** Larger kernel
 46 sizes promote sample structures being better preserved. However, residual stripes
 47 also became more apparent. The effect of tuning it on a zebrafish dataset is given
 48 below.

49
 50 51 52 53 54

Impact of `guided_upsample_kernel`. To better see the effect, we first applied guided upsam-
 pling with different window sizes without ill. prior module (top row). As the window size increased,
 sample structures could be better preserved; however, residual stripes also became more apparent
 (see zoomed-in region). Notably, the ill. prior module (bottom row) enhanced robustness and effec-
 tively suppressed residual stripes across all window sizes.

- 55 ● **`resample_ratio` (int, default = 3):** **Downsampling factor along the stripe di-**
56 **rection used when training the graph neural network (GNN).** The default value
57 (3) provides a good balance between computational efficiency and modeling accu-
58 racy and was used unchanged in all experiments presented in this study. In most
59 applications, modification of this parameter is not required, particularly when the ill.
60 prior is enabled, as structural preservation is then primarily governed by the post-
61 processing module. If the ill. prior is not activated, modest increases in
62 `resample_ratio` (up to 5) may, in some cases, help preserve structural integrity.
63 However, excessively large values may impair the network's ability to model fine
64 stripe patterns and are therefore not recommended.
- 65 *For clarity, other parameters such as the Fourier wedge angle are generally kept at their*
66 *default values; in practice, the user-facing tuning relevant to stripe-suppression/struc-*
67 *ture-preservation trade-offs is primarily controlled by `illu_orient`, `allow_stripe_deviation`,*
68 *and `guided_upsample_kernel` (see parameter definitions above).*
- 69

Recommended practical adjustment procedure
- 70 When parameter refinement is desired, we recommend the following incremental ap-
71 proach:
- 72 1. Start from the default parameter configuration.
- 73 2. Inspect Leonardo-DeStripe's default result that contains both stripe patterns and bi-
74 ologically relevant structures.
- 75 3. If illumination orientation is known and preservation of directionally aligned struc-
76 tures is important, enable the ill. prior via `illu_orient`.
- 77 4. If residual stripe patterns remain visible:
- 78 a) When stripes are irregular (e.g., tilted, wavy, or drifting), enable al-
79 low_`stripe_deviation`.
- 80 b) If residual artifacts persist, modestly decrease `guided_upsample_kernel` to
81 stronger stripe suppression.
- 82 5. After each adjustment, visually assess whether fine structural features remain con-
83 tinuous and well contrasted.
- 84 6. In rare cases where the ill. prior leads to undesired stripe removal, users may dis-
85 able it.
- 86 Adjustment should stop once stripe artifacts are sufficiently suppressed without no-
87 ticeable distortion of genuine biological structures.

88 **2 Leonardo-Fuse: robustness and practical configuration**

89 Leonardo-Fuse was designed to operate reliably under a fixed default configuration and,
90 in typical applications, does not require parameter tuning. All fusion results presented in
91 this work were obtained using default settings. Parameter modification is generally con-
92 sidered only for improving computational efficiency or for accommodating specific da-
93 taset characteristics, such as highly sparse samples or extremely large volumetric da-
94 tases.

95 **Segmentation-related configuration**

- 96 ● `require_segmentation (bool, default = True)`. Segmentation is primarily used
97 to exclude background regions and suppress ghost artifacts near sample bounda-
98 ries during fusion. Thus, when ghost artifacts are not severe, segmentation can be
99 safely disabled to reduce runtime. Also, if the data is highly sparse, no segmenta-
100 tion is advised.

101 **Fusion boundary estimation**

- 102 ● `resample_ratio (int, default = 2)`: **Downsampling factor for estimating the fu-**
103 **sion boundary**. Increasing this value reduces memory usage and computational
104 cost and generally works well for datasets with smooth or slowly varying structures.
105 In routine applications, modification is not required. For large volumetric datasets or
106 resource-limited systems, moderate increases may accelerate processing while
107 maintaining stable fusion behavior.

108 **Registration-related configuration (dual-sided detection)**

109 When dual-sided detection requires registration, Leonardo-Fuse performs internal align-
110 ment prior to fusion. Default registration settings are sufficient in most cases. Registra-
111 tion-related parameters primarily control computational cost and refinement behavior.
112 Adjustment may be considered when:

- 113 ● reliable pre-computed registration results are available (e.g., multi-channel scenar-
114 ios),
115 ● faster execution is desired for large datasets (by increasing axial or lateral
116 downsampling), or
117 ● fine-tuning refinement is unnecessary.

118 Appropriate settings should maintain accurate spatial alignment between views
119 without introducing visible misregistration artifacts in the fused volume. Visual inspection
120 of anatomical continuity across the fusion boundary provides a practical means of as-
121 sessing alignment quality.
